Deployment Guide: Technical Docs Search API

This guide describes how to deploy the search API to a Kubernetes cluster. The service is packaged as a Docker image, configured through environment variables and backed by a PostgreSQL 16 database with the unaccent extension enabled.

1. Prerequisites
A namespace with access to the container registry, a PostgreSQL instance reachable from the cluster, and a secret holding DATABASE_URL. The pg-boss schema is created automatically on boot.

2. Procedimiento de despliegue
Aplique el chart de Helm con los valores del entorno. Verifique las sondas de readiness antes de enrutar tráfico. Si la migración falla, el pod termina con error y el despliegue anterior permanece activo.

3. Verification
GET /health must report database "up". Upload a sample document and confirm it reaches the INDEXED state within a few seconds; the search_vector column is populated by PostgreSQL itself.
